(57) ABSTRACT

A balloon inflator includes a tank containing a volume of pressurized gas and a regulator assembly removably secured to the tank for reducing the pressure of gas exiting the tank, the regulator assembly including a pressure regulator. A nozzle assembly is also provided and includes a valve for controlling dispensing of the pressurized gas. A flexible hose extends between the regulator assembly and the nozzle assembly, the hose being in fluid communication with the pressure regulator and the valve. The balloon inflator is small and lightweight, and therefore portable and concealable. The flexible nature of the hose allows for easy manipulation of the nozzle assembly, making use of the balloon inflator easier for performers.

FIG. 3

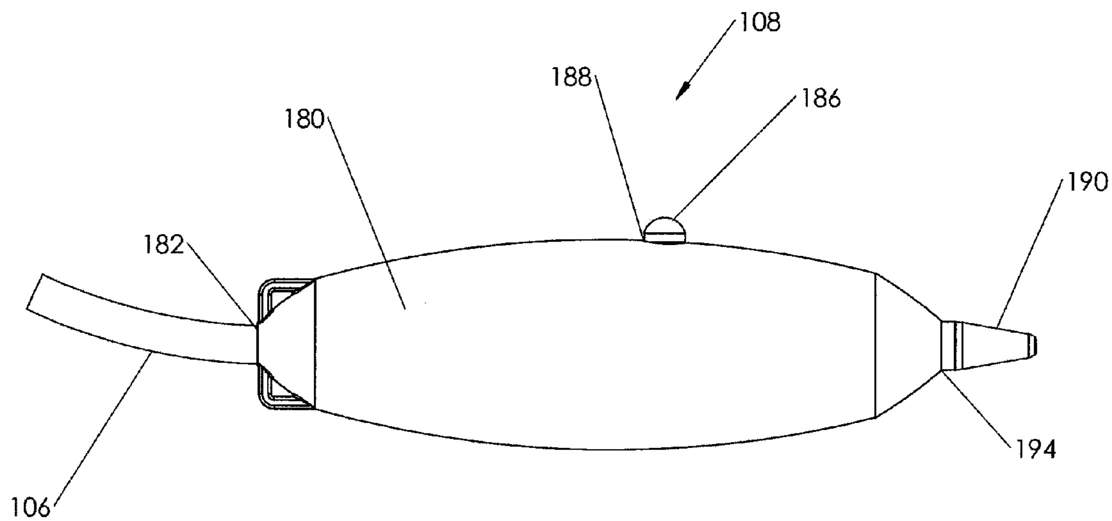

FIG. 4

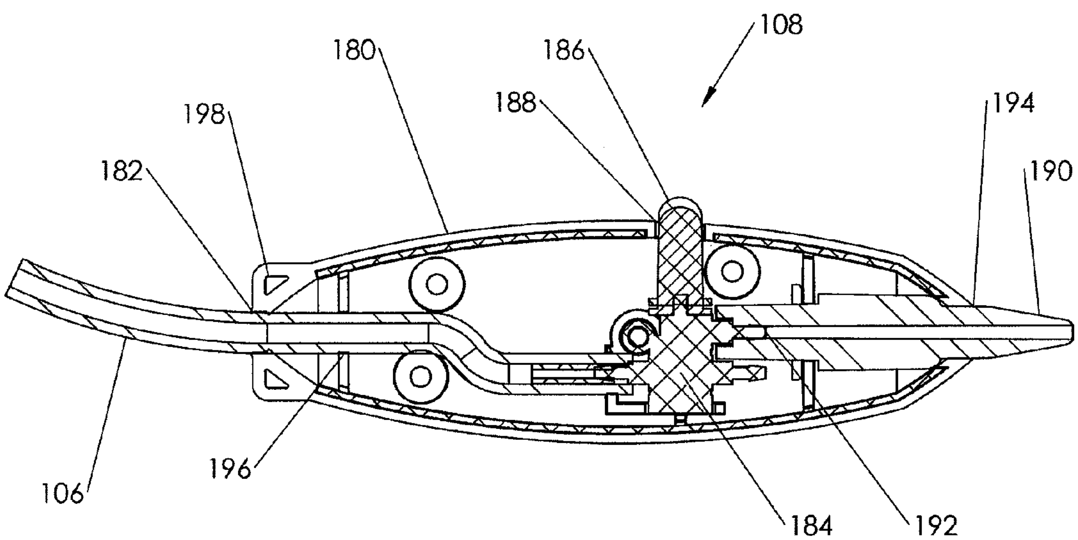

FIG. 5

BALLOON INFLATOR

FIELD OF THE INVENTION

The present disclosure relates generally to balloon inflators. More particularly, the present disclosure relates to a portable, pressurized tank-based balloon inflator. The balloon inflator is able to fill various balloons, but in particular embodiments is intended to fill modeling balloons.

BACKGROUND OF THE INVENTION

The use of balloons as decorations for parties, celebrations, grand openings, and other events is well known, and millions of balloons are so used each year. In many instances, performers use balloons for entertainment purposes. For example, balloon artists, known in the industry as "twisters," create shapes and animals from "modeling" balloons specifically designed for that purpose. Modeling balloons are long and have a small diameter, but are very strong and resilient in order to withstand all the twisting. Only individuals with extremely strong lungs can generate the air pressures necessary to blow up modeling balloons (and particularly those of high quality), and it is therefore helpful, and sometimes necessary, to inflate them using a balloon inflation device or "balloon inflator". Many varieties of balloon inflators are known and commercially available, but these inflators suffer from a number of disadvantages, particularly where the performer moves about during the performance, making portability an issue.

Prior art balloon inflators capable of generating the pressures necessary for inflating a modeling balloon are motor based, typically employing a motor to power an air compressor or a pump. The motors, compressors and/or pumps make these balloon inflators heavy and cause them to become hot while operating. In addition, motor-based balloon inflators can be somewhat large and awkward in size, making them cumbersome and difficult to carry. Furthermore, prior art balloon inflators may overheat if used or run continuously. All of these factors weigh against easy portability. The prior art portable modeling balloon inflators rely upon batteries for power. Batteries are a burden because they must be recharged or replaced when they no longer provide sufficient power. They also suffer from requiring frequent replacement, especially during frequent use. These battery powered devices often also suffer from electrical complications.

A particular prior art balloon inflator that is commercially available utilizes a compressor similar to those used in automobile horns to inflate modeling balloons. This compressor is not designed for continuous use, but instead is designed for use in short durations, and is therefore not ideally suited for use as a balloon inflator. In addition, the compressor is typically powered by a nickel cadmium battery or lead-acid battery, which are both heavy and expensive. Therefore, this popular balloon inflator suffers from a number of disadvantages.

Thus, there is a need for an improved portable balloon inflator device that alleviates one or more of the deficiencies discussed above. Notably, although this need relates most specifically to modeling balloons, the balloon inflators taught herein can generally inflate any type of balloon.

SUMMARY OF THE INVENTION

In general, a balloon inflator according to the present disclosure includes a tank containing a volume of pressurized gas; a regulator assembly removably secured to said tank for

reducing the pressure of gas exiting the tank, the regulator assembly including a pressure regulator; a nozzle assembly including a valve for controlling dispensing of the pressurized gas; and a hose extending between said regulator assembly and said nozzle assembly, said hose being in fluid communication with said pressure regulator and said valve.

In other embodiments, a balloon inflator of this invention includes a tank containing a volume of pressurized gas and including a valve assembly having a valve and a first pressure regulator for reducing the pressure of gas leaving said tank; a regulator assembly removably secured to said tank for reducing the pressure of gas exiting the tank, the regulator assembly including a second pressure regulator; a nozzle assembly including a valve for controlling dispensing of the pressurized gas, a nozzle for dispensing pressurized gas, and a housing positioned around said valve and said nozzle; and a flexible hose in fluid communication with said second pressure regulator and said valve.

Yet other embodiments of this invention provide a method of "magically" inflating a balloon using a balloon inflator. This method includes the steps of securing a tank and regulator assembly of the balloon inflator to an article worn by a user; positioning a hose of the balloon inflator beneath the clothes of the user; securing a nozzle assembly of the balloon inflator in or adjacent to a hand of the user; positioning an open end of a balloon over a nozzle of the nozzle assembly while keeping the presence of the nozzle assembly hidden; pressing an actuating button on the nozzle assembly to release a volume of pressurized gas into the balloon; and tying the balloon closed without revealing the nozzle assembly.

BRIEF DESCRIPTION OF THE DRAWINGS

For a full understanding of the apparatus and methods of the present disclosure reference should be made to the following detailed description and the accompanying drawings, wherein:

FIG. **1** is a perspective view of a balloon inflator according to the concepts of the present disclosure.

FIG. **2** is a side view of a tank, regulator assembly, and a portion of a hose extending from the regulator assembly according to the concepts of the present disclosure.

FIG. **3** is a section view of the tank, the regulator assembly, and the portion of the hose extending from the regulator assembly as shown in FIG. **2**.

FIG. **4** is a side view of a nozzle assembly and a portion of the hose entering the nozzle assembly according to the concepts of the present disclosure.

FIG. **5** is a section view of the nozzle assembly of FIG. **4**.

DETAILED DESCRIPTION OF THE ILLUSTRATIVE EMBODIMENTS

With reference to FIGS. **1-5**, it can be seen that a balloon inflator according to this disclosure is designated generally by the numeral **100**. Balloon inflator **100** includes a tank **102**, a regulator assembly **104**, a hose **106**, and a nozzle assembly **108**. The hose **106** extends between regulator assembly **104** and nozzle assembly **108** to transmit pressurized gas therebetween. The hose **106** can be of any desired length. The balloon inflator is small in size and is powered by pressurized gas within the tank **102**. Notably, the balloon inflator **100** is devoid of a motor, devoid of an air compressor or air pump, and is devoid of batteries, which were necessary in the prior art to power the motors, compressors and/or pumps. The balloon inflator **100** is most preferably portable. The hose **106** and nozzle assembly **108** make the balloon inflator **100** easy to use, even for performers using the device during a performance.

The tank **102** of balloon inflator **100** contains a volume of pressurized gas suitable for filling balloons. The gas may be any desired gas, and will typically be selected based upon the intended use. The most typically gases are air and helium. Tank **102** may be generally cylindrical in shape, and includes a bottom surface **110**, a sidewall **112**, and a neck portion **114**. In certain embodiments, bottom surface **110** may be generally planar for providing a suitable surface for the tank **102** to rest upon. While a generally cylindrical tank is shown in the drawings and described herein, it is also contemplated that tanks having various other sizes and shapes may be utilized with the balloon inflator of the present disclosure.

A valve member **120** (FIG. **3**) is secured to tank **102** at neck portion **114** to fluidly communicate with the pressurized content therein. Valve member **120** includes first stage regulator **122** and a valve **124**. In certain embodiments, valve member **120** may be provided as an integral part of tank **102**. First stage regulator **122** reduces the pressure of pressurized gas leaving tank **102**. First stage regulator **122** may be any suitable regulator known to those skilled in the art. For example, the regulator may include a piston regulator and a spring biasing the piston, where pressure acting on the exposed surface area of the piston is balanced by the spring force. Valve **124** controls the release of pressurized gas from tank **102**. The valve **124** may be any suitable valve known to those skilled in the art. In certain embodiments, valve **124** may be a standard ASA pin valve having external threads **126** on an exterior surface consistent with ASTM F-1750.

In one or more embodiments, valve member **120** may also include one or more additional ports and/or gauges, as will be appreciated by those skilled in the art. For example, valve member **120** may include a fill valve **128** fluidly communicating with the internal volume of the tank **102** for optionally refilling the tank **102** with pressurized gas when the tank is empty or the pressure of the gas therein is reduced below a useful pressure. In addition, a safety plug **130** fluidly communicating with the internal volume of the tank **102** may optionally be provided to allow release of gas and pressure if a dangerous internal pressure is reached within the tank. A pressure gauge **132** (FIG. **2**) can fluidly communicate with the contents of tank **102** for determining the pressure within the tank **102** and/or the approximate amount of pressurized gas remaining within tank **102**. In certain embodiments, an on/off valve may also be provided to selectively control the flow of pressurized gas from the tank **102**. Such valves are well known to those skilled in the art.

Regulator assembly **104** includes a second stage regulator **140** and an adapter **142** to connect the first and second stage regulators **122** and **140** so that they fluidly communicate with one another. In one or more embodiments, the second stage regulator **140** may be similar in structure and operation to first stage regulator **122**. In certain embodiments, the second stage regulator further reduces the pressure of gas flowing from the first stage regulator to a pressure suitable for use in filling balloons.

The adapter **142** is connected to the valve member **120** and the second stage regulator **140**. In the embodiment shown in the drawings, the adapter **142** includes a first recess **144** containing internal threads **146** and a second recess **148** containing internal threads **150**. Internal threads **146** of first recess **144** mate with external threads **152** provided on a connector portion of the second stage regulator **140**. Similarly, the internal threads **150** of second recess **148** mate with the male threads **126** on valve member **120**. The adapter **142** also includes a passage **154** there through to allow pressurized gas to move from the valve member **120** through second stage regulator **140**. When the regulator assembly **104** is secured to the valve member **120**, the valve **124** is actuated by the adapter **142** to allow gas to flow from the tank **102** through the first stage regulator **102**, the valve **124**, the adapter **142**, and the second stage regulator **140**.

A gas, now reduced in pressure a second time to a level suitable for inflating balloons, exits second stage regulator **140** at an exit port **156** and flows through the hose **106** to the nozzle assembly **108**. The hose **106** is connected to the regulator assembly **104** at the exit port **156** of second stage regulator **140**. The hose **106** may have any desired length and diameter suitable for the intended purpose. In addition, the hose **106** may be made of any known material suitable for the intended use. In a preferred embodiment, the hose **106** is flexible in nature so as to allow for maneuverability of the nozzle assembly **108**, as will be discussed below. In one or more embodiments, the hose **106** may be made of a natural or synthetic rubber composition.

Regulator assembly **104** further includes a housing **160** that surrounds and protects the components of the regulator assembly **104**. Housing **160** includes a first opening **162** adjacent to the second recess **148** to allow the housing **160** and adapter **142** to be received over the valve member **120** and the male threads **126** of tank **102**. First opening **162** may be circular in shape to facilitate rotation of the regulator assembly **104** relative to the tank **102**. The housing **160** also includes a second opening **164** adapted to allow the hose **106** to extend therethrough. In certain embodiments, the second opening **164** may be positioned opposite the first opening **162**. The second opening **164** may also be circular in shape to accommodate the generally cylindrical hose **106**, and a radius **166** may be provided on the outer surface of second opening **164** to protect the hose **106** from flexing.

Housing **160** may further include a belt clip **168** either formed integrally therewith or otherwise secured thereto. Belt clip **168** includes a clip surface **170** and a clip arm **172** biased to be in close proximity to the clip surface **170**. In some embodiments, as here, it extends generally parallel to the clip surface **170**. In one or more embodiments, the clip arm **172** may include a radiused connecting arm **174** extending from an edge of the clip surface **170**. As will be appreciated by those skilled in the art, clip arm **172** is capable of flexing relative to clip surface **170** to allow a belt or other article to slide between the clip surface **170** and the clip arm **172** and be wedged therebetween to hold the balloon inflator **100** on such belt or article. In certain embodiments, an angled end portion **176** of the clip arm **172** helps to facilitate clipping of the belt clip **168** to an article by providing a mouth for insertion of such article.

In one or more embodiments, housing **160** may also include one or more hose supports **178** therein that prevent excessive strain from acting on the hose **106**. In the embodiment shown in the drawings, hose supports **178** are cross members extending across the internal cavity of housing **160**, each hose support **178** having an aperture **179** therethrough that receives a portion of hose **106**. The number and spacing of the hose supports **178** may vary as necessary to adequately support the hose **106** based upon the specific design of the housing **160** and the properties of the hose.

Referring to FIGS. **4** and **5**, nozzle assembly **108** includes an ergonomic housing **180** that contains and protects the components therein. Housing **180** includes a first opening **182** sized and shaped to receive an end of the hose **106**. The hose **106** extends through the first opening **182** and is connected to a valve **184**, actuation of which causes pressurized gas to be dispensed from the nozzle assembly **108**. Valve **184** includes a valve actuator **186** that allows a user to control opening and closing of the valve **184**. In the embodiment shown, the valve actuator **186** is a push button extending through an aperture **188** in housing **180**. Valve **184** may be any suitable valve known to those skilled in the art and capable of controlling the flow of pressurized gas from the tank **102** and through the hose **106** and nozzle assembly **108**. A nozzle **190** is in fluid communication with an outlet **192** of the valve **184**. Nozzle **190** defines a second opening **194** in housing **180**, and is sized and shaped to receive a neck portion of a balloon thereon for filling.

The housing **180** of nozzle assembly **108** may also include one or more hose supports **196** adjacent to first opening **182** to alleviate the strain placed upon hose **106**. In addition, the housing **180** may include integral loops **198** that allow for attachment of a ring to the nozzle assembly **108**. The ring (not shown) attached to the integral loops **198** provides a grip for one or more fingers to allow a user to secure the nozzle assembly **108** within a hand while allowing them to continue to use that hand to manipulate a balloon. While a specific nozzle assembly design has been shown, it will be appreciated by those skilled in the art that various modifications can be made to the nozzle assembly within the scope of the present disclosure.

The tank **102** can be designed with various volumes and pressures, and will be designed with an eye toward the volume of gas it can provide at an appropriate pressure to fill the desired type of balloon. The first and second stage regulators **122**, **140** are also taken into account in designing the balloon inflator **100**. In one or more embodiments, the tank volume is less than 1500 cubic centimeters, in other embodiments, less than 1250 cubic centimeters, in yet other embodiments, less than 1000 cubic centimeters, and, in yet other embodiments, less than 800 cubic centimeters. In one or more embodiments, the tank volume is greater than 400 cubic centimeters, in other embodiments greater than 500 cubic centimeters, in yet other embodiments, greater than 600 cubic centimeters, and in still other embodiments greater than 700 cubic centimeters.

Within such volume ranges, the tank may be pressurized to various pressures of gas. In one or more embodiments in which the tank is pressurized with gas, such as, for example, air or helium, the pressure of the tank may be greater than 6,894.75 kPa (1,000 psi), in other embodiments greater than 8,000 kPa (1,160.30 psi), in yet other embodiments, greater than 10,000 kPa (1,450.38 psi), and in still other embodiments, greater than 15,000 kPa (2,175.57 psi). In one or more embodiments in which the tank is pressurized with gas (e.g. air or helium), the pressure of the tank may be less than 34,473.80 kPa (5,000 psi), in other embodiments less than 33,000 kPa (4,786.25 psi), in yet other embodiments less than 30,000 kPa (4,351.13 psi), and in still other embodiments less than 25,000 kPa (3,625.94 psi). It is also contemplated that where other gasses are used, such as, for example, carbon dioxide, the pressures within the tank may be higher or lower to prevent the gas from changing phase or for other considerations. For example, where carbon dioxide is used, the pressure of the tank may be approximately 5,515.81 kPa (800 psi).

In one or more embodiments, the first stage regulator reduces the pressure of the gas to less than 10,000 kPa (1,450.38 psi), in other embodiments less than 9,000 kPa (1,305.34 psi), in other embodiments less than 8,000 kPa (1,160.30 psi), in other embodiments less than 7,000 kPa (1,015.26 psi), in other embodiments less than 6,000 kPa (870.23 psi), in other embodiments less than 5,000 kPa (725.19 psi), in still other embodiments less than 4,000 kPa (580.15 psi), and in yet other embodiments less than 3,000 kPa (435.11 psi).

In one or more embodiments, the second stage regulator reduces the pressure of the gas to less than 1,000 kPa (145.04 psi), in other embodiments less than 900 kPa (130.53 psi), in other embodiments less than 800 kPa (116.03 psi), in other embodiments less than 700 kPa (101.53 psi), in other embodiments less than 600 kPa (87.02 psi), in other embodiments less than 550 kPa (79.77 psi), in still other embodiments less than 500 kPa (72.52 psi), and in yet other embodiments less than 400 kPa (58.02 psi).

In certain embodiments, the tank may have a volume of between 400 and 1250 cubic centimeters, and is pressurized with air to a pressure of from 6,894.75 kPa to 34,473.8 kPa (1,000-5,000 psi). In the same or other embodiments, the first stage regulator may reduce the pressure of gas exiting the tank to a pressure that is between 5,000 and 6,000 kPa, and the second stage regulator may further reduce the pressure of gas traveling to the nozzle assembly to between 650 and 750 kPa. In a particular embodiment, the tank may have a volume of approximately 786 cubic centimeters, and is pressurized to a pressure of approximately 20,684.28 kPa (3,000 psi). The first stage regulator may reduce the pressure to approximately 5,515.8 kPa (800 psi), and the second stage regulator may reduce the pressure to approximately 689.48 kPa (100 psi).

The tank and other elements are preferably chosen with an eye toward reduced weight. In one or more embodiments, the entire filled balloon inflator assembly **100** is less than 3.5 kilograms (kg), in other embodiments less than 2.5 kg, in yet other embodiments less than 1.5 kg, and in still other embodiments less than 1.0 kg.

In one or more embodiments, operation of the balloon inflator **100** creates noise having a decibel level of less than 50 dB, in other embodiments less than 40 dB, in yet other embodiments less than 30 dB, and in still other embodiments less than 20 dB. These low decibel levels are not experienced in those balloon inflators employing motors and air compressors, which are notably absent in embodiments of the present invention. Also absent are batteries necessary to operate such motors and air compressors. Though batteries might be employed in embodiments of the balloon inflator of the present invention for adding additional features to the balloon inflator, such as, for example, lights or graphic displays.

As is apparent from the description above, a balloon inflator **100**, according to the concepts of the present disclosure is highly portable and is easy to manipulate and use. The belt clip of the regulator assembly housing allows for easy and convenient attachment of the tank **102** and the regulator assembly **104** to a users clothing or belt. In certain embodiments, the size of the tank **102** is chosen to allow for easy concealment of the balloon inflator **100**. The flexible hose **106** allows a user to secure the nozzle assembly **108** in a convenient location without concern for the tank **102** and regulator assembly **104**. For instance, a user may clip the tank **102** to a belt and run the hose **106** beneath clothing so that the nozzle assembly **108** can be held or "palmed" in a hand without the tank **102**, hose **106** and nozzle assembly **108** being visible. The loop **198**, and the ring that may be secured thereto, allow a user to continue using two hands to manipulate a balloon without having to set aside or store a nozzle assembly **108**.

A method of using the balloon inflator **100** to inflate a balloon will now be described. The balloon inflator **100** may be secured to a users belt or clothing in an area capable of concealment. The hose **106** may be run beneath the users clothing and though a sleeve and the nozzle assembly **108** may be held or positioned in or adjacent to a users hand. The user may hold a balloon with one or both hands and, without letting an audience see, secure the end of the balloon over the nozzle **190** and press the valve actuator **106** to inflate the balloon. Because the tank **102**, regulator assembly **104**, hose **106**, and nozzle assembly **108** all remain hidden from view, the inflation of the balloon may be made to look like "magic." Release of the valve actuator **186** will close valve **184** to stop pressurized gas from flowing from tank **102**. The user may then tie the balloon and manipulate the balloon as necessary with the nozzle assembly **108** being secured in or near the users hand by a ring secured to the loops **198**. Of course, hiding the hose and nozzle is not required.

As is apparent from the above description, a balloon inflator as described herein does not require a motor or pump, and therefore does not require an electric cord or batteries. Accordingly, the balloon inflator makes less noise, does not generate heat, and is smaller in size than conventional balloon inflators. In addition, a balloon inflator as described herein may be easily hidden and manipulated due to the inclusion of the hose and separate nozzle assembly. The tank of the balloon inflator may be easily refilled if desired, or replaced with a full tank if refilling is not convenient.

It is thus evident that a balloon inflator constructed as described herein substantially improves the art. Only particular embodiment(s) have been presented and described in detail, and the invention should not be limited by the drawings or the description provided. For an appreciation of the true scope and breadth of the invention, reference should be made only to the following claims.

The invention claimed is:

1. A body-worn balloon inflator comprising:

(a) a tank containing a volume of pressurized gas and including a valve assembly having a first valve and a first pressure regulator for reducing the pressure of gas leaving said tank; and a

(b) a tank receiver separate and distinct from said tank and valve assembly, said tank receiver including:

(1) a regulator assembly including a second pressure regulator, a regulator assembly housing, and a belt clip extending from said housing,

(2) a nozzle assembly including a second valve for controlling dispensing of the pressurized gas, a nozzle for dispensing pressurized gas, and a nozzle assembly housing positioned around said second valve and said nozzle; and

(3) a flexible hose in fluid communication with said second pressure regulator and said second valve, wherein said tank receiver removably receives said tank by mating of said regulator assembly and said valve assembly of said tank, such that, when said tank is empty, a new tank and valve assembly can replace the empty tank.

2. The body-worn balloon inflator of claim **1**, wherein said nozzle assembly housing is ergonomic in shape.

3. The body-worn balloon inflator of claim **1**, said pressurized gas within said tank having a pressure of between approximately 1000 and 5000 psi.

4. The body-worn balloon inflator of claim **1**, said first pressure regulator reducing the pressure of said pressurized gas to less than 1000 psi.

5. The body-worn balloon inflator of claim **4**, said second pressure regulator in said regulator assembly reducing the pressure of said pressurized gas to less than 150 psi.

6. The body-worn balloon inflator of claim **1**, said regulator assembly further comprising an adapter secured to said valve assembly of said tank and said second pressure regulator of said regulator assembly, said adapter allowing for fluid communication between said valve assembly and said second pressure regulator.

7. The body-worn balloon inflator of claim **1**, said regulator assembly housing having an opening to allow said hose to extend from said second pressure regulator to said second valve, said opening including a radiused circumferential surface to prevent flexing of the hose.

8. The body-worn balloon inflator of claim **1**, said regulator assembly housing including one or more hose supports for reducing strain upon the hose.

9. The body-worn balloon inflator of claim **1**, wherein the balloon inflator is devoid of a motor and air compressor.

10. The body-worn balloon inflator of claim **1**, said second valve including an actuating mechanism for opening said second valve to dispense pressurized gas, said actuating mechanism extending through an aperture in said regulator assembly housing.

* * * * *
